Part 1 — HTML & CSS

Topics Covered

- HTML document structure, including head, body, metadata, and viewport settings.
- Semantic elements: header, nav, main, section, footer, aside, and article.
- Content elements: headings, lists, links, images, and tables.
- Forms: input types, labels, select, textarea, buttons, and built-in validation.
- Accessibility: alternative text, form labels, keyboard focus, and colour contrast.
- CSS fundamentals: selectors, specificity, box model, colours, units, and fonts.
- Page layout with Flexbox and Grid, plus responsive design using media queries.

Key Learnings

- Semantic markup improves accessibility, SEO, and maintainability; use a div only when no suitable semantic element exists.
- Every form field needs an associated label. A placeholder is not a replacement for a label.
- Native HTML validation attributes such as required, type, pattern, and minlength can reduce the need for JavaScript validation.
- Provide an alt attribute for every image; use alt="" for decorative images.
- :focus-visible supports keyboard accessibility without unnecessarily showing focus rings after mouse clicks.
- Text should meet WCAG contrast minimums: 4.5:1 for normal text and 3:1 for large text.
- CSS specificity is evaluated by ID, class, and type selectors. Keeping specificity low and predictable helps avoid !important.
- Applying box-sizing: border-box globally makes element sizing more predictable.
- Use rem for font sizes and spacing to better respect user preferences.
- Flexbox is suited to one-dimensional layouts, while Grid is suited to two-dimensional layouts.
- A mobile-first approach uses base styles for smaller screens and min-width media queries to enhance larger layouts.

Part 2 — QA Manual Testing

Topics Covered

- Agile Testing Quadrants; Three Amigos sessions; Definition of Ready (DoR) and Definition of Done (DoD).
- Acceptance criteria using Given/When/Then (Gherkin).
- Browser DevTools: Elements, Console, Network, and Application panels.
- Cookies, Local Storage, Session Storage, and IndexedDB.
- Browser cache behaviour, HTTP cache headers, and responsive view testing.

Key Learnings

- The four Agile Testing Quadrants balance preventive testing (Q1/Q2) and detective testing (Q3/Q4); an effective team needs all four.
- Three Amigos brings business, development, and testing perspectives together to clarify requirements before implementation.

- DoR determines whether a story is ready to enter a sprint; DoD defines the verifiable conditions required for completion.
- Gherkin scenarios should use business language, focus on observable outcomes, and generally contain one When action.
- DevTools Elements helps inspect the rendered DOM and accessibility attributes; Console reveals JavaScript errors; Network shows requests, responses, status codes, and cache headers; Application exposes cookies and browser storage.
- Session cookies should use appropriate security attributes such as HttpOnly and Secure. Sensitive authentication tokens should not be stored in Local Storage.
- Disabling the browser cache is useful during development, but it does not replace testing cache behaviour and correctness.
- Responsive testing checks content reflow, touch target size (at least 44 × 44 px as a practical target), truncation, orientation, and usability at 200% zoom.

Summary

Today I strengthened my HTML and CSS foundation by working with semantic page structure, accessible forms, CSS fundamentals, Flexbox, Grid, and responsive layouts. I also learned practical QA approaches covering Agile Testing Quadrants, Three Amigos, DoR/DoD, Gherkin acceptance criteria, browser DevTools, browser storage, cache behaviour, and responsive testing.

Practical progress: Completed hands-on exercises for semantic and accessible web pages, Gherkin acceptance criteria, DevTools inspection, cache verification, and responsive layout auditing. The related work will be maintained in the GitHub repository listed above.
